

### Midterm - Lab Activity2\_ The Javascript Basics

The main difference is that Java is an object-oriented, statically typed, and compiled language, while JavaScript is a dynamically typed, interpreted scripting language. This distinction affects how each language is written and executed.

|                        | Java  | JavaScript  |
|------------------------|---|---|
| <b>Function Syntax</b> | <ul style="list-style-type: none"><li>• Functions are always defined <b>inside classes</b> as methods.</li><li>• Each method must have an <b>access modifier</b> (public, private, etc.), a <b>return type</b> (int, String, void), and <b>parameter types</b>.</li><li>• Java requires explicit data types for both parameters and return values.</li><li>• Methods are enclosed in curly braces {} and cannot exist outside a class.</li><li>• Supports <b>method overloading</b>, allowing methods with the same name but different parameters.</li><li>• Java is <b>statically typed</b>, meaning errors are checked during compilation.</li></ul> <p><b>Example:</b><br/><pre>public static void greet(String name) {<br/>    System.out.println("Hello " + name);<br/>}</pre></p> | <ul style="list-style-type: none"><li>• Functions can exist <b>outside of classes</b> and do not require access modifiers.</li><li>• Declared using the function keyword, <b>function expressions</b>, or <b>arrow functions</b> (=&gt;).</li><li>• No need to declare data types for parameters or return values.</li><li>• JavaScript is <b>dynamically typed</b>, so types are determined at runtime.</li><li>• Functions are <b>first-class objects</b> they can be stored in variables, passed as arguments, or returned by other functions.</li><li>• More flexible and less strict than Java in syntax and structure.</li></ul> <p><b>Example:</b><br/><pre>function greet(name) {<br/>    console.log("Hello " + name);<br/>}</pre></p> |
| <b>Calling Methods</b> | <ul style="list-style-type: none"><li>• Methods are called using an <b>object</b> or <b>class name</b>.</li><li>• Syntax: <code>object.methodName(args);</code> or <code>ClassName.staticMethod(args);</code></li><li>• The number and type of arguments must exactly match the method definition.</li><li>• Java enforces <b>compile-time type checking</b>, preventing mismatched data types.</li><li>• Code execution must occur within methods standalone code is not allowed.</li></ul> <p><b>Example:</b><br/><pre>Person p = new Person();<br/>p.greet("Tasha");</pre></p>   | <ul style="list-style-type: none"><li>• Functions can be called <b>directly by name</b> or as methods of an object.</li><li>• Syntax: <code>functionName(args);</code> or <code>object.method(args);</code></li><li>• JavaScript allows <b>flexible arguments</b> extra ones are ignored, missing ones become undefined.</li><li>• Functions can use <code>.call()</code> or <code>.apply()</code> to change the context (this).</li><li>• Code can run <b>outside functions</b>, such as directly in the browser console or script.</li></ul> <p><b>Example:</b><br/><pre>greet("Tasha");</pre></p>  |

|                   |   |  |
|-------------------|---|--|
| <b>Statements</b> | <ul style="list-style-type: none"><li>• Requires <b>explicit data types</b> for variable declarations (e.g., int, String, double).<br/>Example: int age = 25;</li><li>• Statements must exist <b>inside methods</b> or class blocks.</li><li>• Uses common control flow statements: if, else, switch, for, while, do-while.</li><li>• Supports enhanced for-each loops.</li><li>• Java is <b>statically and strongly typed</b>, so variables cannot change types once declared.</li><li>• Supports <b>multithreading</b> for parallel execution of tasks.</li><li>.</li></ul> | <ul style="list-style-type: none"><li>• Variables are declared using var, let, or const <b>no type declaration</b> needed.<br/>Example: let age = 25;</li><li>• Code can run globally (outside of functions or objects).</li><li>• Uses the same control flow structures as Java: if, else, switch, for, while.</li><li>• Variables declared with let and const are <b>block-scoped</b>; var is <b>function-scoped</b>.</li><li>• <b>Dynamically typed</b> variable types can change during runtime.</li><li>• Follows an <b>event-based concurrency model</b> using callbacks, promises, and async functions.</li></ul> |
|-------------------|---|--|
